## Introduction

### 1.1 Background

The Northern Territory Government (NTG) has proposed an expansion of the East Arm Wharf (EAW) in Darwin Harbour to accommodate the requirements of prospective wharf users, including commercial users and the Department of Defence. The major features of the project (refer **Figure 1-1**) are as follows:

- Developing a Marine Supply Base (MSB), primarily to service the existing and developing oil and gas industries in the Timor Sea, Browse Basin and adjacent areas.
- Constructing a Multi User Barge Facility (MUBF) including a barge ramp and hardstand area, berthing for barges and facilities for loading and unloading.
- Development of a facility to accommodate tugs, customs boats and other smaller vessels.

The EAW Expansion Project was subject to an Environmental Impact Assessment (EIA) and an Environmental Impact Statement (EIS) was developed to investigate the potential impacts of the development on the surrounding marine and terrestrial environments (DLP 2011a; DLP 2011b). The EIS was submitted to the Northern Territory (NT) Environmental Protection Agency (EPA) and the Department of Environment<sup>1</sup> (DoE) for consideration.

The project received approval under the NT Environmental Assessment Act 1982 in December 2011 and conditional approval by DoE under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) in March 2012 in the form of Approval EPBC 2010/5304.

A document, *East Arm Wharf Expansion Project (EPBC 2010/5304), Revision of the Multi-user Barge Ramp Facility* (URS, 2013), has been recently submitted advising the DoE and the NT EPA of the changes to the proposed MUBF location. An alternative tug and small vessel facility location is currently being considered with communications to the relevant agencies to follow.

This sampling and analysis plan (SAP) has been prepared for the dredging required for the revised MUBF location and addresses the requirements set out in Conditions 24 and 25 of the Commonwealth project approval (EPBC 2010/5304) under sections 130(1) and 133 of the EPBC Act.

### 1.2 Multi User Barge Facility

The MUBF will be used for the berthing of barges and loading or unloading of cargo and equipment. The general operations of cargo consolidation, loading and unloading would comprise the greatest use of the facility. It is anticipated that on occasions, tracked vehicles (tanks) and munitions could be loaded (with appropriate temporary buffers) prior to military exercises and then unloaded after the exercises. Similarly, an emergency response operation could initiate significant use of the barge ramp and laydown area (Department of Lands and Planning [DLP] 2011). Under certain emergency circumstances, Defence may have full use of the facility for a period of time and all other users would be excluded.

The hardstand will function as a storage area for barge operators. It is anticipated that one or two barge operators would typically be operating from the barge ramp at any given time, and loads would be stored on site for up to 48 hours (prior to transfer to a barge). A marshalling area on the ramp will be included to facilitate loading and unloading of vehicles. Information presented in this section was derived from and is based on the report *Defence Barge Ramp Option 144* prepared for DLP by Aurecon (2012).

<sup>1</sup> Formerly Commonwealth Department of Sustainability, Environment, Water, Population and Communities

## 1 Introduction

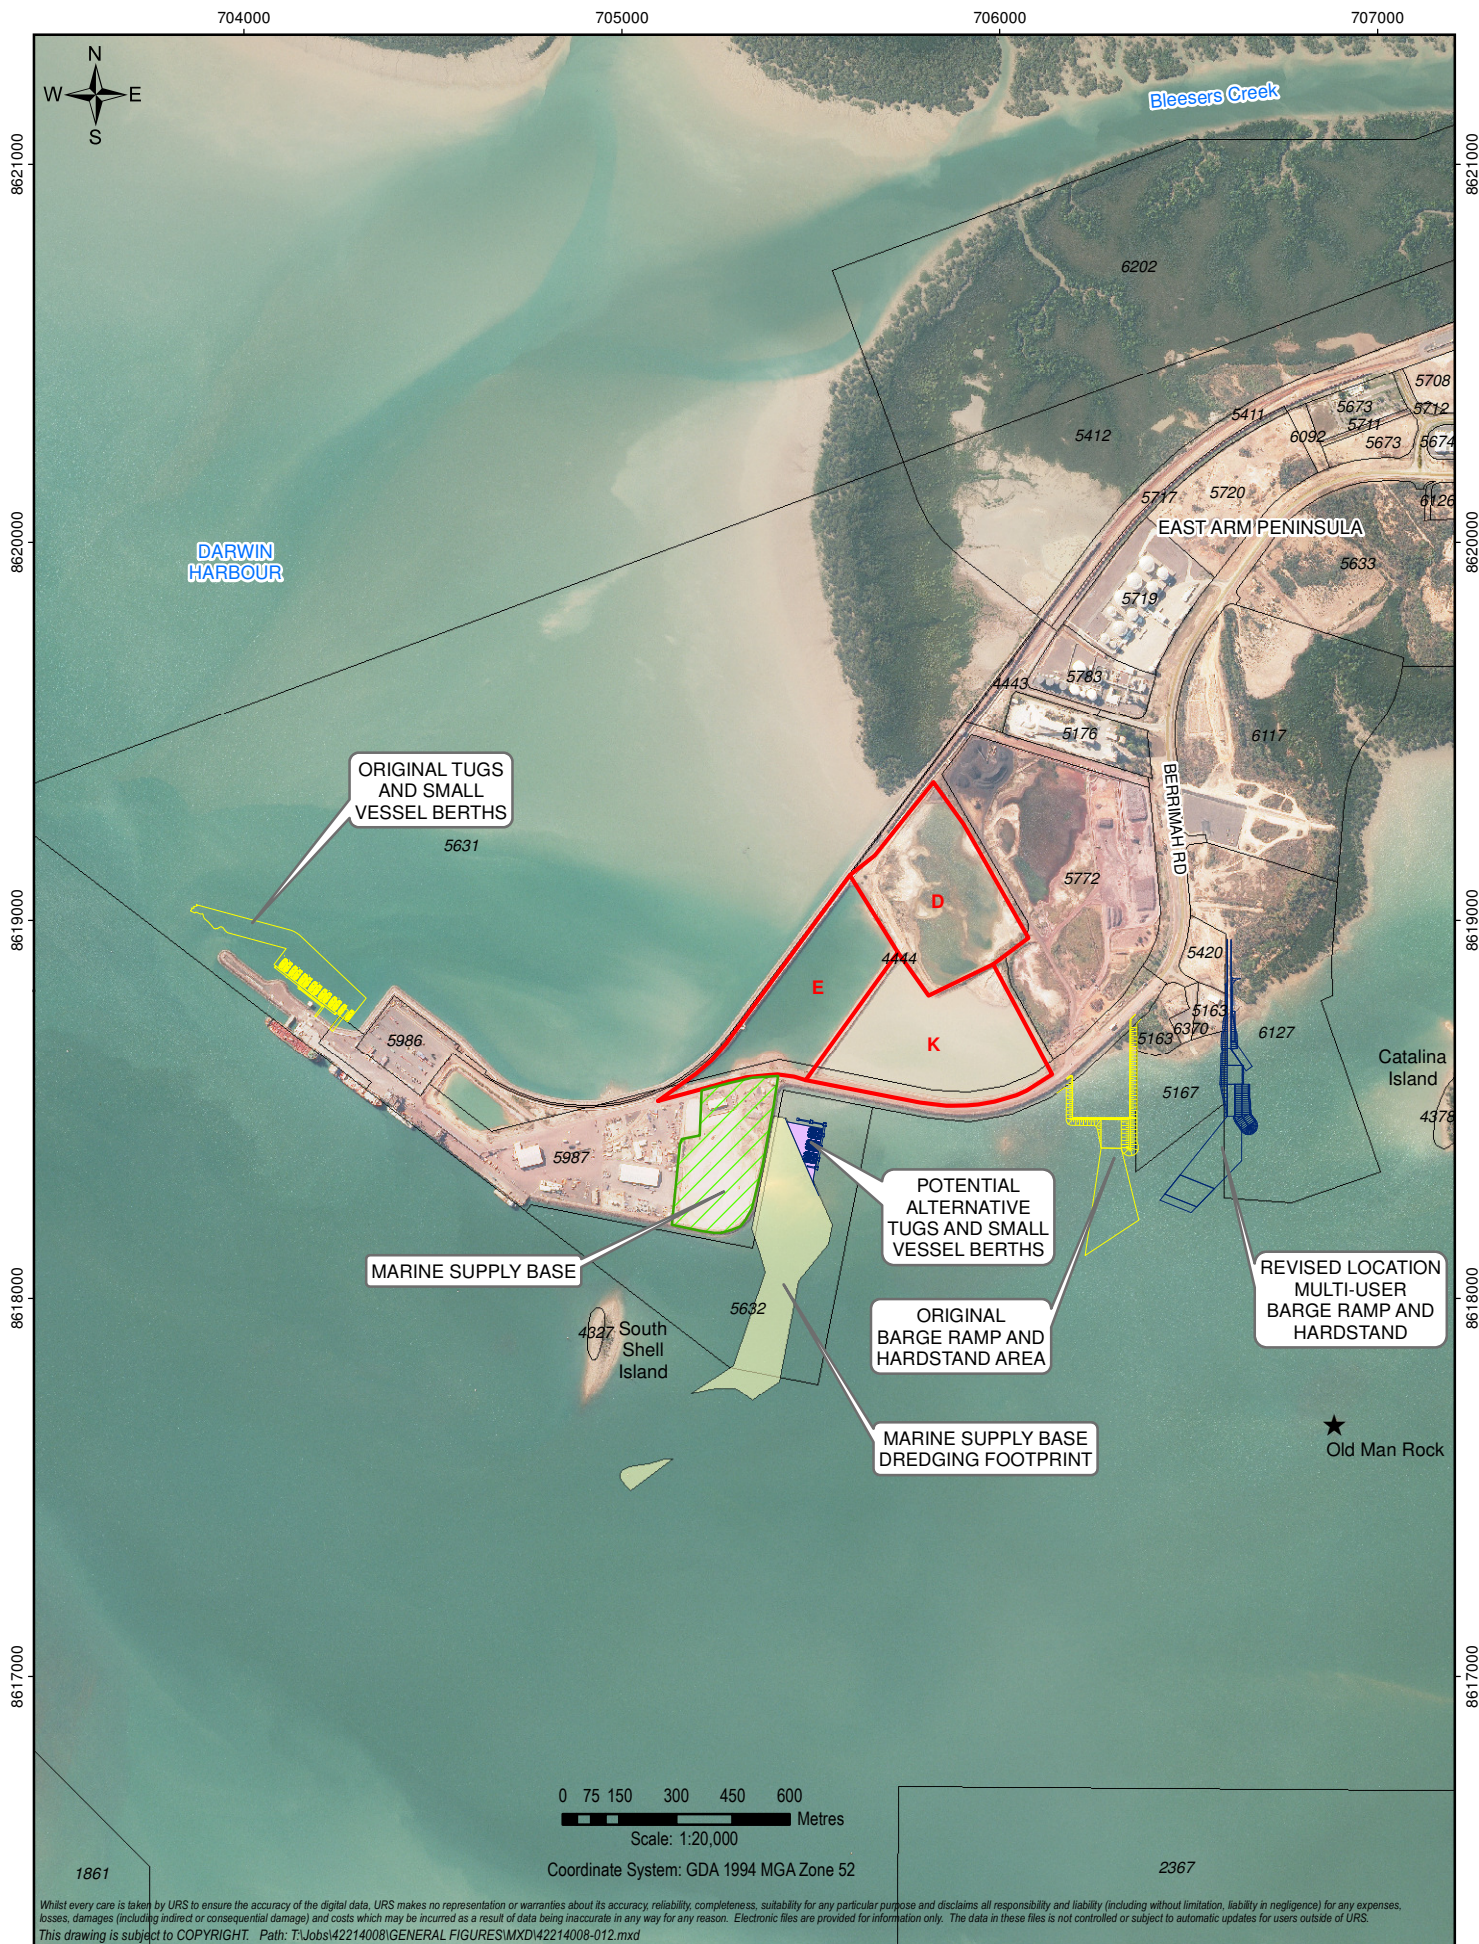

**Figure 1-1** shows the revised location of the MUBF, which is situated on the southern side of East Arm peninsula; approximately 200 m east of the original location. The revised location site is owned by the Land Development Corporation (LDC). The facility will be accessed via a new access road from south of the existing drain to the proposed ramp site, connecting it with Berrimah Road and providing strategic access to the EAW, rail freight terminal and Darwin Business Park. A fence and gates are proposed to ensure controlled access to the MUBF.

The MUBF concept design (**Figure 1-2**) incorporates the following features:

- A dredged channel to -1.1 m CD (Chart Datum) to provide access to the barge ramp at most tide levels for vessels up to design vessel size (23.3 m length, 6.4 m beam and maximum draft of 1.2 m).
- Onshore marshalling area 80 m x 100 m and a loading area 40 m x 50 m.
- Rock wall to provide protection to the reclaimed land forming the ramp access and a breakwater to provide protection to vessels at the end of the ramp. The breakwater and structure orientation has been designed to achieve the required currents of less than 1 knot.
- Access road to hardstand area.
- Power and fire-fighting water systems.

The bathymetry and the benthic habitats surrounding the MUBF are also detailed on **Figure 1-2**.

## EAW EXPANSION PROJECT COMPONENTS

### MULTI USER BARGE FACILITY DREDGING SAP

## 1 Introduction

### 1.3 Proposed dredging

Dredging for the MUBF approach channel and footprint is to be conducted by a cutter suction dredge (CSD). The two proposed dredge zones are depicted in **Figure 1-3**.

It is proposed that the CSD will undertake initial dredging of the shallow portion of the approach channel followed by the western side of the footprint and then the eastern side of the footprint.

The soft sediments under the MUBF footprint will be dredged down to bedrock to prevent mud waving. The dredge volume for the proposed project will be approximately 16,000 m<sup>3</sup>.

The preferred location for dredge spoil disposal is within the existing ponds at East Arm Wharf (outlined in red in **Figure 1-1**) which have a capacity large enough to accommodate the volume of dredge spoil to be generated. The features of the program are detailed in **Table 1-1**.

**Table 1-1 Planned MUBF dredging campaign details**

Feature	
Vessel type	CSD
Dredge depth	- 1.1 m CD
Estimated dredge footprint	25,426.7 m <sup>2</sup>
Estimated dredge volume	16,000 m <sup>3</sup>
Estimated 'soft' materials volume	16,000 m <sup>3</sup>
Average discharge rate – soft sediment	750 m <sup>3</sup> per hour*
Average discharge rate – consolidated material (if any)	450 m <sup>3</sup> per hour*
Pumping details	Approximately 12% solids*
Fine material discharge loss	Approximately 1%*

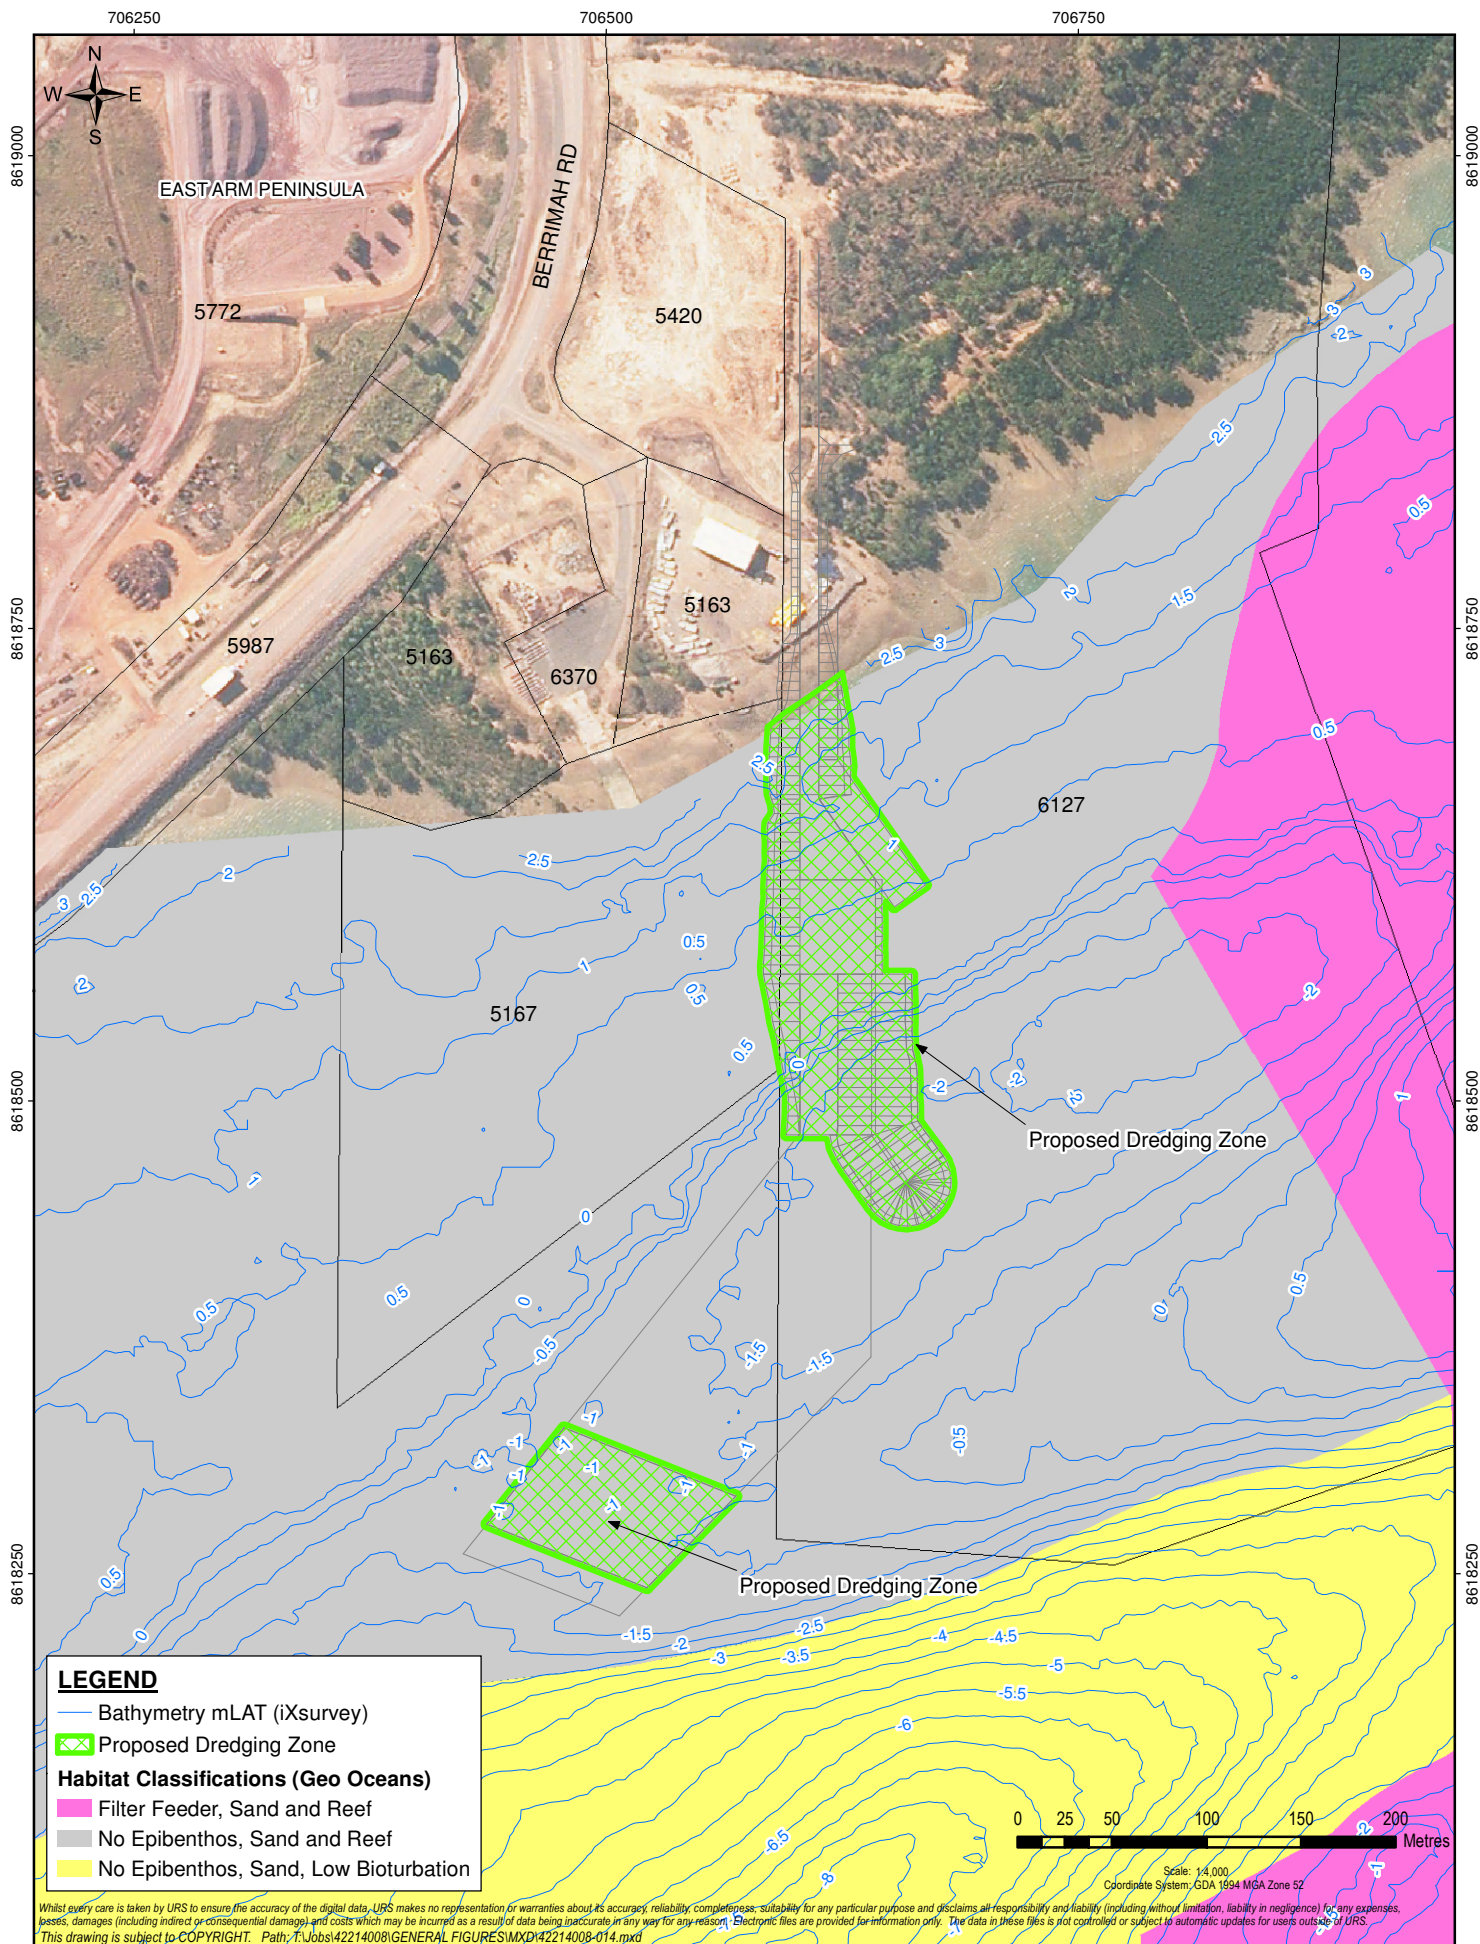

\*Based on estimates for the CSD Eastern Aurora which was used for dredging the MSB component of this development

An accurate indication of the composition of the sediments to be dredged is not currently available and this SAP has been prepared on the basis that all material to be dredged is unconsolidated sediments (muds, clays and sand). Nearby geotechnical surveys at the MSB dredge area (approximately 1 km west of the MUBF location and depicted in **Figure 1-1**) showed unconsolidated sediments (muds, clays and sand), underlain with low strength phyllite and low – medium strength meta-siltstone.

Boreholes drilled historically in the MSB dredge area indicate:

- below the RL -3 mCD contour indicate dredging will be in up to 4 m of soft sediments and overburden soils with only a less than 0.5 m depth of low strength phyllite
- above the RL -3 mCD contour there could be 5.2 m of overburden soils, then up to 1.8 metres of low – medium strength meta-siltstone. There could be about 3.5 m of overburden soils, then 3 m of very low to low strength meta-siltstone to the limit of drilling at RL-1.3 m CD. (AECOM 2011).

## MUBF DREDGING ZONE

## 1 Introduction

### 1.4 Proposed investigation

URS Australia Pty Ltd (URS) has been commissioned by the LDC to develop this SAP with reference to the *National Assessment Guidelines for Dredging* (NAGD) (Commonwealth of Australia 2009). The SAP assesses the proposed dredging program and available historical data on the physical and chemical characteristics of sediments in the vicinity of the MUBF and access channel (Phase I assessment). In addition, the sampling and analysis of sediments for contaminants listed on the Contaminants List (Section 3.2) and a comparison to Screening Levels (Phase II assessment) are detailed in the Sampling Methods (Section 5).

Elutriate and bioavailability testing (Phase III) and assessment of toxicity and bioaccumulation (Phase IV) may not be required, depending on the outcomes of the Phase II assessments. However, if necessary, Phase III and Phase IV assessments will be undertaken in the event that the upper 95% confidence limit of mean concentrations of contaminants in sediment exceed NAGD Screening Levels.

Geochemical testing of sediments in the dredging zones is proposed to assess the distribution and variability of contaminant concentrations and to compare these concentrations to Screening Level values in the NAGD (Commonwealth of Australia 2009). The data will be used to classify the sediments in a single dredge management unit or, if required, to define several distinct dredge management units.

### 1.5 Objectives

The purpose of this SAP is to describe the location and number of seafloor sediment samples, the sampling methodology, analytical and sample transport procedures to assess the physical and chemical characteristics of the sediments proposed to be dredged.

Specifically, investigations to support the proposed dredging program at EAW have the following objectives:

- Complete a field sampling and analytical program of sediment proposed for dredging in accordance with guidance provided in the NAGD (Commonwealth of Australia 2009).
- Determine whether the quality and quantity of data gathered are sufficient to adequately characterise the contamination status of the sediments to assess disposal and re-use options.

Data quality objectives for the program are:

- To collect and retain, in accordance with the SAP procedures, the required number of cores and samples to assess contamination levels in accordance with the NAGD (Commonwealth of Australia 2009).
- To collect and retain, in accordance with the SAP procedures, the required number of quality assurance/quality control (QA/QC) samples to assess data quality in accordance with the NAGD (Commonwealth of Australia 2009).
- For analysis of the samples to be undertaken at a National Association of Testing Authorities (NATA) accredited laboratory in accordance with laboratory QA/QC procedures and NAGD (Commonwealth of Australia 2009) analysis procedures.
- For the SAP report to undergo independent detail checks and technical reviews before the results are provided to DoE and utilised in the Water Quality Management Plan for the project, as detailed in Conditions 26 and 28 of the Commonwealth project approval (EPBC 2010/5304).

## 1 Introduction

### 1.6 SAP Review and Approval

This SAP has been reviewed and approved for release to the client by Ian Baxter of URS, who is a member of the Consultancy Panel for DoE, for whom reviews are undertaken of documents submitted in support of applications for the disposal of dredged material (under the *Environment Protection [Sea Dumping] Act 1981*).

For ease of review of this SAP by the Commonwealth Department of the Environment (DoE), Appendix A of the SAP details in which sections of the SAP that the relevant guidance provided in Appendix B of the NAGD (Commonwealth of Australia 2009) has been addressed.

## Environmental Setting

### 2.1 Darwin Harbour

#### 2.1.1 Physical characteristics

Darwin Harbour is a large ria system, or drowned river valley, formed by post-glacial marine flooding of a dissected plateau. The harbour was formed by rising sea levels about 6000-8000 years ago and has a surface area variously described as between 500 and 1,000 km<sup>2</sup>, depending upon the boundaries applied (e.g. Padovan 2001, Darwin Harbour Advisory Committee [DHAC] 2003; INPEX 2010; DLP 2011). In its southern and south-eastern portions, the harbour has three main components: East, West and Middle Arms which merge into a single unit, along with the smaller Woods Inlet, before opening into Beagle Gulf to the north.

The harbour extends for more than 30 km along this north-north-east – south-south-westerly oriented axis. The Elizabeth River flows into East Arm, while the Darwin and Blackmore rivers flow into Middle Arm. During the dry season (May to September) the estuary is typically well mixed, but freshwater inflow from rivers during the wet season can lead to stratification of salinity in the water column in the arms of the harbour (Drewry et al. 2010).

The Darwin Harbour catchment is some 2,417 km<sup>2</sup>, which is relatively small when compared to its estuary area of some 810 km<sup>2</sup> (DHAC 2003; Wolanski et al. 2005). The relatively low catchment to estuary ratio (when compared to other major Australian estuaries) was considered by DHAC (2003) to indicate that there is less potential for disturbance from runoff to the estuary than in estuaries with proportionally larger catchments.

#### 2.1.2 Land use and contaminant loads

DHAC (2003), based on the data of Owen and Meakin (2003), determined that there was a wide diversity of land uses within the Darwin Harbour region, though almost 70% of the region was occupied by non-polluting uses (e.g. remnant native vegetation, surface water supply, conservation areas).

The Elizabeth River has the second largest catchment of the rivers entering Darwin Harbour [the largest is the Blackmore River that enters Middle Arm (Padovan 2001)]. In the late 1990s, rural land use accounted for approximately 75% of the catchment area. This is likely to have increased over the past decade, being primarily comprised of rural residential areas and small-scale horticultural developments in the upper reaches of the river. Undeveloped land (predominantly mangrove communities) fringes the river over a distance of some 25 km between the rural land use areas and East Arm, has the potential to act as a buffer to reduce the amounts of contaminants reaching East Arm from sources in the upper catchment. Padovan (2001) calculated the mean annual contaminant loads contributed to the harbour from the Elizabeth River catchment in the mid-1990s to be 69 tonnes of nitrogen, 3.5 tonnes of phosphorous, 70 kg of arsenic, 14 kg of cadmium, 156 kg of chromium, 373 kg of copper, 132 kg of lead, 138 kg of nickel and 1,638 kg of zinc.

Approximately 6 km upstream of EAW, the Palmerston Wastewater Treatment Plant discharges treated effluent into Myrmidon Creek, which enters the lower reaches of the Elizabeth River where it enters East Arm. The mass loadings of the release from the Plant in 2005/06 were 40 tonnes of ammonia, 69 tonnes of Kjeldahl nitrogen and 18 tonnes of phosphorus (Power and Water Corporation [PWC] 2006).

## 2 Environmental Setting

Some 3 km upstream of the MUBF dredging area is Hudson Creek, which supports livestock export facilities and other light industrial uses. The Hudson Creek catchment also includes rural and urban land. All of these land uses represent potential sources of contaminants that may accumulate in the MSB dredging area. In the mid-1990s, the mean annual contaminant loads contributed to the harbour from the Hudson Creek catchment were calculated by Padovan (2001) to be 15 tonnes of nitrogen, 3 tonnes of phosphorous, 40 kg of arsenic, 6 kg of cadmium, 220 kg of chromium, 189 kg of copper, 327 g of lead, 43 kg of nickel and 1,860 kg of zinc.

It is understood, based on a number of previous studies (Section 3.1), that arsenic is present in the region at concentrations potentially above screening levels as a result of the local geology, however bioavailable levels are low (refer Table 3-1).

### 2.1.3 Distribution of contaminants

Environmental factors that may potentially affect the distribution of contaminants within Darwin Harbour, and hence could influence the concentrations of contaminants in the sediments of the MUBF dredging area, include:

- Strong tidal currents that readily mobilise seafloor sediments on flood and ebb tides, especially during spring tide periods.
- Eddies in water flows that enhance the settlement of sediments from the water column in certain areas (such as at the eastern end of EAW).
- Wind-driven water circulation that can redistribute large amounts of seafloor sediments, particularly during tropical storms and cyclones.

Each of these factors would primarily influence the distribution of fine sediment fractions, to which metals are typically bound at higher densities (Batley 1995).

## 2.2 East Arm Wharf

EAW is located approximately 4.5 km south east of the Darwin Central Business District (CBD). Opened in 2000, the existing wharf has a continuous 754 m berth face located parallel to the main shipping channel, and incorporates a dry bulk materials handling facility featuring a ship loader designed to load Panamax class vessels and is currently used to export iron ore, manganese, and copper concentrate. EAW occupies a land area of approximately 18 ha of sealed hard stand surface with 4,000 m<sup>2</sup> of undercover cargo handling facility, and a further 18 ha of bunded area for future reclamation. A single rail spur from the Australasia Railway runs over a 16 m wide railway causeway, linking to three rail lines to the wharf (including a 4 ha intermodal container terminal), with road access provided over the causeway from Berrimah Road (NTG 2011).

The primary role of EAW is to facilitate the movement of goods via rail, road and shipping to international markets. EAW currently services vessels handling general cargoes, live cattle exports, dry bulk imports, containerised / break bulk and specialised heavy lift cargoes, plus offshore rig tender service vessels (AECOM 2009). It is utilised by oil and gas, mining, agriculture, horticulture, bulk minerals and construction industries [Darwin Port Corporation (DPC) 2010].

The types and tonnages of cargo imported and exported from Darwin Port in 2012/2013 are detailed in **Table 2-1** (DPC 2013). Of note with reference to potential impacts on sediment quality are ores, minerals, chemicals and petroleum. These have historically influenced the sediment quality in the EAW area, most notably after copper concentrate spills occurred while loading in 2010 (AIMS 2010).

## 2 Environmental Setting

**Table 2-1 Trade through Darwin Port in 2012/2013**

Commodity	Export tonnage	Import tonnage
Beverages	22	4,921

## Existing Data

### 3.1 Previous investigations

The NAGD (Commonwealth of Australia 2009) state that existing chemical or toxicity data for the sediments of the area to be dredged have a maximum currency of five years, where there is no reason to believe that the contamination status has changed significantly, after which new data are required. The EAW area was subject to copper concentrate spills in 2010 (AIMS 2010), so in accordance with the guidelines, all data from 2010 and earlier are to be used for historical comparison only and cannot be used to characterise the current contaminant status of the sediments to be dredged.

Previous investigations that were conducted in the vicinity of EAW (though not within the MUBF dredging area) include the following:

- URS, 2012, East Arm Wharf Dredging Sampling and Analysis Plan and report, prepared for Northern Territory DLP in April 2012.
- AIMS 2010, Investigation of Copper Concentrate Loadout at East Arm Port: Water and Sediment Quality, prepared for Northern Territory Government Department of Natural Resources, Environment, the Arts and Sports, Darwin, Northern Territory.
- URS, 2009, Ichthys Gas Field Development Project: Nearshore Marine Water Quality and Sediment Study. Prepared for INPEX Browse, Ltd, 11 August 2009.
- Fortune, J, 2006. The grainsize and heavy metal content of sediment in Darwin Harbour. Report No. 14/2006D of the Aquatic Health Unit, Environmental Protection Agency, Department of Natural Resources, Environment and the Arts, Darwin, Northern Territory.

The findings of the previous investigations will assist in consideration of the potential sources of contaminants to the EAW area. Selected findings (sediment quality exceedances only) from these studies are summarised in **Table 3-1**.

**Table 3-1 Sediment sampling results from selected previous studies in the East Arm Wharf area**

Study	Analyte	Screening Level (mg/kg)	95% UCL	Comment
URS 2012	Arsenic	20	42.2	Bioavailability = low
AIMS 2010	Arsenic	20	Not calculated	Screening Level exceeded at some sites near EAW
	Copper	270	Not calculated	Exceeded at some sites near EAW. One site exceeded ANZECC bioavailability criteria.
URS 2009	Arsenic	20	37.2	Bioavailability = low
	Chromium	80	45.1	Screening Level exceeded at some sites near EAW
	Mercury	0.15	0.018	
	Nickel	21	5.9	
Fortune 2006	Arsenic	20	Not calculated	Screening Level exceeded at two sites near EAW

### 3 Existing Data

These studies found that although the NAGD Screening Levels were exceeded at some individual sites, the only 95% UCL level to exceed a Screening Level was arsenic in the URS (2009) study (in which elutriate testing showed that arsenic was present in a form with only low bioavailability). Other analytes investigated in these studies did not exceed Screening Levels at any site. The URS (2012) study results showed a 95% UCL level for arsenic above the Screening Level but the distribution of arsenic within the sediment profile suggests the elevated levels are still attributable to the local geology.

#### 3.2 Contaminants list

Taking into consideration port activities, potential catchment inputs and data from previous sediment sampling programs in East Arm, **Table 3-2** presents a list of contaminants which it is considered could be present at elevated levels in the sediments within the MUBF dredging area. In addition to the listed contaminants, samples will also be tested for acid sulfate soils potential, as required by the conditions of the Commonwealth project approval.

**Table 3-2 Contaminants list for sampling in MUBF dredging area**

Analytical Parameter	Rationale for Analysis
Particle Size Distribution Analysis (PSD)	Standard sediment analysis tool.
Total Organic Carbon (TOC)	For normalisation of organics
Antimony	Potentially found at ore export loading facilities
Aluminium	Useful for normalising elements
Arsenic	Known to be naturally high background levels
Cadmium	Common pollutant in port areas
Chromium	Elevated concentrations detected by URS (2009)
Copper	AIMS (2010) indicated the presence of elevated concentrations in port sediments
Iron	Exported from EAW
Lead	Common pollutant in port areas
Manganese	Exported from EAW
Mercury	Elevated concentrations detected by URS (2009)
Nickel	Elevated concentrations detected by URS (2009)
Silver	Common pollutant in port areas
Zinc	Common pollutant in port areas
Total polycyclic aromatic hydrocarbons (PAHs)	Common pollutant in port areas
Total petroleum hydrocarbons (TPHs)	Common pollutant in port areas
Total nitrogen	Palmerston wastewater treatment outfall located upstream

### 3 Existing Data

Analytical Parameter	Rationale for Analysis
Total phosphorus	Phosphate rock exported from EAW
Tributyltin (TBT)	No longer used as an antifoulant, but still potentially present in port environments.
Radionuclides	Uranium and thorium exported from EAW

It should be noted that not all of the “typical sediment contaminants” listed in Table 1 of the NAGD (Commonwealth of Australia 2009) appear in Table 3-2 of this SAP. Contaminants for which there are considered to be no significant sources of input to the MUBF dredging area (e.g. from imports or exports, or from the surrounding catchment) have been excluded from Table 3-2. For example, while organochlorine pesticides (mainly dieldrin) were detected in some samples of Darwin stormwater in the mid-1990s by Padovan (2001), these pesticides have been progressively phased out over the subsequent decades. Therefore it is considered that the potential for organochlorine pesticides to be present in the MUBF dredging area sediments is sufficiently low to justify their exclusion from the contaminants list.

This page has been intentionally left blank

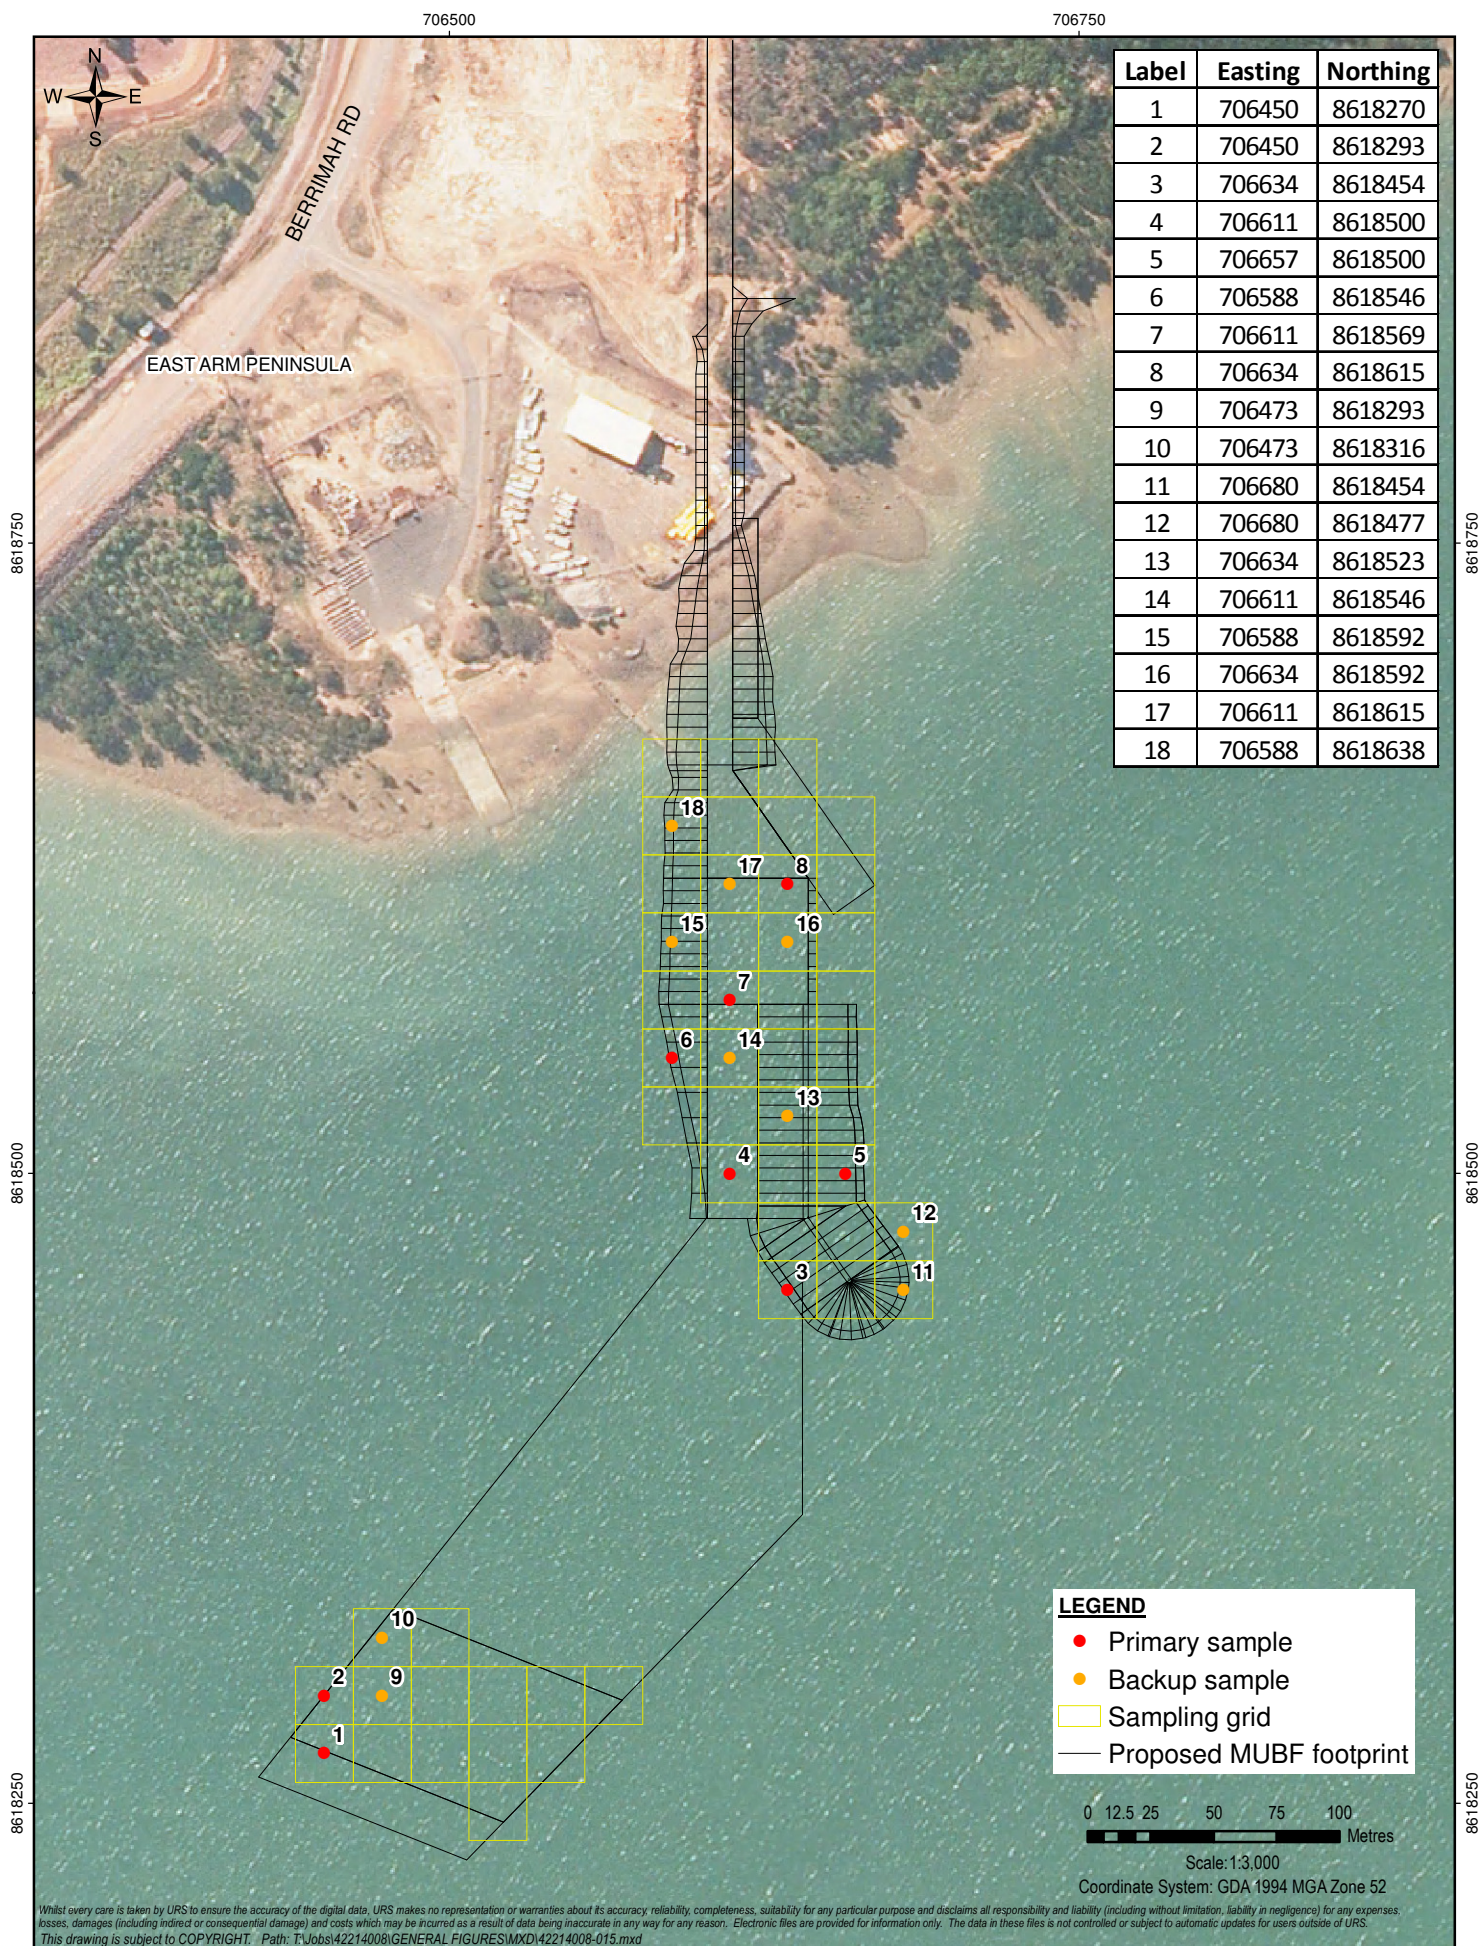

## Sampling Locations

The required number of sample locations, calculated in accordance with Appendix D of the NAGD, is seven. However, the expected dredge volume of 16,000 m<sup>3</sup> is close to the 17,000 m<sup>3</sup> volume where eight sample locations are required. For this reason, eight locations will be sampled as a precautionary measure to ensure compliance with the NAGD. The estimated volume of sediment to be dredged was derived by the EAW expansion project construction contractor.

As indicated in Appendix D of the NAGD, “contaminants... will rarely penetrate far into the underlying, undisturbed geological materials, especially if these are clay or rock”. In the absence of complete geotechnical survey information at the time of writing, as a precautionary measure this SAP assumes the entire volume of 16,000 m<sup>3</sup> of sediment to be dredged is unconsolidated.

The locations were selected by overlaying a 35 x 35m grid over the dredging area (to provide a total of 45 cells, more than the 40 cells [5 x 8 sample locations] needed to meet the requirements of Appendix D of the NAGD), then generating random numbers to determine the cells within which samples are to be collected. The sampling locations and coordinates (in geodetic datum GDA94) are shown in **Figure 4-1**. An additional 10 locations and coordinates are also shown; these will be sampled as required in the event that any of the initial eight locations do not have a surface layer of unconsolidated sediments.

**SAMPLING LOCATIONS MAP  
AND GPS COORDINATES**

## Sampling Methods

### 5.1 Sterilisation procedures

Prior to commencement of sampling operations, an area on the vessel will be designated for sample handling. Potential contaminant sources in the vicinity of this area (e.g. galvanised or oily surfaces) are to be covered to reduce the potential for sample contamination.

Field personnel will wear sterile disposable nitrile gloves during sampling to minimise the potential for sample contamination by residues (e.g. hydrocarbons, sunscreen, etc.). Gloves will be changed between samples. Sterile plastic and stainless steel spatulas will be used where direct contact with the sediment sample is necessary (e.g. during splitting of the cores): stainless steel will be used for samples to be analysed for organic compounds, and plastic for samples to be analysed for metals. Smoking is not permitted in the vicinity of, or upwind from, the designated sample processing area. Sample processing will be undertaken upwind of generators and any other engines that are unable to be turned off for safety reasons.

The polycarbonate core tubing to be used for sample collection (see Section 5.2) will be cleaned with dilute acid, then rinsed with deionised water and a suitable solvent before the commencement of the sampling program. Sampling equipment will be decontaminated between sites by thorough cleaning in seawater. If clayey sediments are encountered, then a Decon solution will be used to clean the cores, with the cores rinsed in seawater prior to use at the next site.

### 5.2 Sampling methods

All sampling will be undertaken using a vibrocore. This will be installed on a vessel fitted with appropriate lifting equipment, power generation, deck space, shallow draft, adequate station-holding capability and other specifications to be finalised by the coring equipment supplier. The equipment will be manned by suitably qualified and experienced personnel, and the field operations supplemented by geotechnical staff from the contractor. The cores, with polycarbonate liners, are driven into the seabed from the vessel, then recovered to the vessel.

Aboard the support vessel, the sediment will be extruded from the core and photographed. The depth and visual descriptions of the sediment will be recorded, including colour, predominant grain size, presence of shell fragments and depth of any distinct horizons (changes in colour or grain size). Composite samples will be taken from every 0.5 m horizon, i.e. 0–0.5 m; 0.5–1.0 m, etc. Any intermediate horizons of soft sediments >0.5 m in thickness will be sampled separately.

### 5.3 Sample handling, preservation and transport

**Table 5-1** details the containers, holding times and possible analysing laboratories for each analyte. Sediment samples will be placed in 250 ml laboratory supplied glass jars (for hydrocarbons and TBT analyses) and plastic whirlpak bags (for metals, PSD and acid sulfate soils analyses). The use of plastic, rather than glass, storage containers is recommended for metals, as metals tend to adsorb onto glass surfaces, potentially leading to underestimates of metal concentrations. An additional whirlpak of sediment will be retained at each site for archiving purposes.

All samples (whirlpaks and jars) will be placed inside labelled plastic self-seal bags for protection, stored on ice or refrigerated in the field and frozen at the earliest opportunity. Samples will be delivered, with accompanying Chain of Custody forms, to a NATA accredited laboratory for analysis.

## 5 Sampling Methods

**Table 5-1 Practical Quantification Limit (PQLs) and analytical methods**

Analyte	PQL	Method	Container / sediment weight	Holding time	Lab
<b>Total Petroleum Hydrocarbons (TPH)</b>	2 – 100 mg/kg	GC-FID-EP071	Teflon Lined 250 ml Glass Jar 100-250 g	14 days chilled to 4°C Extended if frozen	ALS
<b>Total Polycyclic Aromatic Hydrocarbons (PAH)</b>	0.004-0.005 mg/kg	USEPA 3640/8270	Teflon Lined 250 ml Glass Jar 100-250 g	14 days	ALS
<b>Metals</b>					
Antimony	0.5mg/kg	USEPA 6020 ICP/MS  and  EG020SDH	Whirlpak  10-100 g	180 days chilled to 4°C Extended if frozen	ALS
Arsenic	0.5 mg/kg				
Cadmium	0.1 mg/kg				
Chromium	0.5 mg/kg				
Copper	0.5 mg/kg				
Lead	1 mg/kg				
Nickel	1 mg/kg				
Zinc	0.5 mg/kg				
Iron	2 mg/kg				
Aluminium	5 mg/kg				
Mercury	0.01 mg/kg	APHA 3112 Hg-B CV/FIMS			
<b>Tributyltin (TBT)</b>	1 µg Sn/kg	GCMS-EP090	Teflon Lined 250 ml Glass Jar 100-250 g	14 days chilled to 4°C 120 days if frozen	ALS
<b>Total Organic Carbon (TOC)</b>	0.1%	LECO after acid treatment – EP005	Teflon Lined 250 ml Glass Jar 10-50 g	Undetermined-extended storage if frozen	
<b>Particle Size Distribution (PSD)</b>	-	Wet sieving and laser diffraction	Whirlpak 50-200 g	No specific holding time – chilled to 4°C	ALS
<b>Radionuclides</b>	500 bq/kg	ISO9696 & ISO9697	Teflon Lined 250ml Glass Jar 50-200 g	6 months	ALS
<b>Total Nitrogen</b>	20 mg/kg	NT-11	Teflon Lined 250ml Glass Jar 50-200 g	6 months	ALS
<b>Total Phosphorus</b>	2 mg/kg	NT-11	Teflon Lined 250ml Glass Jar 50-200 g	6 months	ALS

## 5 Sampling Methods

Analyte	PQL	Method	Container / sediment weight	Holding time	Lab
Acid sulfate soils	Action criteria dependent on clay content. <sup>1</sup>	Chromium suite: Total actual acidity (TAA), Chromium Reducible Sulfur (SCr) and Acid Neutralising Capacity (ANC). <sup>2</sup>	Whirlpak 100-250 g	Lab in 24 hours and frozen as soon as possible	ALS

1 Refer to Section 8.1 in Identification and Investigation of Acid Sulfate Soils and Acidic Landscapes, WA Department of Environment and Conservation Acid Sulfate Soils Guideline Series May 2009.

2 10 % of samples will also be analysed using the Suspension Peroxide Oxidation Combined Acidity and Sulfate (SPOCAS) Suite.

### 5.4 Sample numbers

The total number of samples to be collected cannot be calculated at this juncture, as the number of samples from each location will depend on the depth of unconsolidated sediment at that location.

Following Quality Assurance / Quality Control (QA/QC) practice recommended in the Guidelines, the following samples will be collected:

- Field triplicate samples of sediments at 10% of locations (typically those with plentiful unconsolidated sediments). This will involve collecting and processing three separate samples at one location.
- Field splits at 5% of locations (i.e. one location). The sample will be homogenised and split into three subsamples, two of which will be processed separately by the primary analysing laboratory, with the third subsample sent to an alternate (reference) laboratory for analysis.

Field triplicate samples and splits will be labelled so as to be identifiable by the field environmental contractor, yet unrecognisable as replicates by the analysing laboratory.

As sediment samples will be collected over a number of days, samples will potentially be sent to the receiving laboratory in batches. If this occurs, one sample from the previous batch, an inter-batch duplicate, will be re-sampled to determine analytical variation between batches.

### 5.5 Laboratory analysis of samples

Analysis of sediments will be undertaken by NATA accredited ALS laboratories in Sydney, Newcastle and Brisbane. The methods and analytical PQLs for the analyses are provided in **Table 5-1**; the latter are at or below those recommended in Table 1 of the NAGD.

Laboratory QA/QC procedures will be consistent with those described in Appendix F of the NAGD. That is, for each batch (10-20 samples) or part batch, the following samples will be analysed.

- One laboratory blank sample.
- For metals, one Standard Reference Material, i.e. a sample of certified composition such as MESS-1 or BCSS-1, or BEST-1 (for mercury), or a suitable internal laboratory standard calibrated against a Standard Reference Material. The laboratory standard will be a ground sediment sample, not a liquid sample, to test both the recovery of the extraction procedure and the analysis.
- For organics, one sample spiked with the parameters being determined (or a surrogate spike for certain organics) at a concentration within the linear range of the method being employed. This will

## 5 Sampling Methods

determine whether the recovery rate of the analytical method is adequate or not (i.e. that all the chemicals present in the sample are actually being found in the analysis).

- One replicate sample to determine the precision of the analysis; the standard deviation and coefficient of variation will be documented.

Recoveries of surrogate spikes will be documented and daily calibration data reviewed. The laboratory will review the quality control data and quality assurance documentation and a statement will be made in their report that the data meet the quality objectives specified by the method for that analysis. These will be presented in the laboratory analytical report - i.e. the acceptable recovery range for spikes and Standard Reference Materials and the acceptable range of RPDs on duplicates. All of the quality assurance data (blanks, laboratory duplicates, spikes and Standard Reference Materials) will be reported with the analytical data for each batch of samples analysed. As soon as the analyses are completed the results will be emailed to URS for review so that any unusual values can be queried and, if necessary, reanalysis carried out before the holding time for the samples has expired.

The laboratory QA/QC procedures will be appropriate for the low concentrations expected in marine sediments, which are frequently lower than those required for contaminated site investigations. A clear statement will be made on the Chain of Custody forms accompanying the samples that they are comprised of marine sediments.

### 5.6 Field records

Field notes will include the manual recording of field conditions (weather, tides and currents), site locations, sampling methods, handling and storage methods, field sample numbers, date, time and identity of sampler.

Field description of sediments will include the physical appearance, texture, colour, and presence of foreign material, presence of shell fragments and or biota and stratification. Where multiple samples are collected at a site, notes will be made on the variability between samples. Records will also be made detailing the unique sample identifier for each sample collected.

Chain of Custody forms accompany all samples to the analysing laboratories. Each sample will appear as a separate line item on the form, with the required analyses clearly identified. The consignments will be checked against the Chain of Custody forms by the laboratories and their completeness confirmed by return e-mail.

### 5.7 Health, safety and environment

Prior to the start of fieldwork, a scope specific risk-based health, safety and environment plan (HSEP) will be prepared and reviewed by key project personnel to address potential risks to the health and safety of project personnel and to their operating environment. Factors specific to East Arm include:

- Strong currents
- Large tidal variations (potential vessel grounding)
- Marine wildlife (e.g. crocodiles, stingers)
- Vessel traffic (commercial and recreational)

These factors will be considered with reference to both sampling efficiency and potential health and safety risks. The HSEP will also include issues such as handling and storage of chemicals used in fieldwork, and management of waste.

## 5 Sampling Methods

Safety planning will include job hazard analyses to identify the personnel and equipment requirements of all survey tasks, vessel navigation duties and responsibilities, the use of routine and emergency communication channels, and the development of an Emergency Response Plan to be followed in the event of a serious accident. On-site vessel inductions and other 'tool-box' safety meetings will be conducted before the start of each sampling task.

### 5.8 Contingency plan

In the event of adverse weather conditions or critical equipment failure rendering the sampling programme unsafe, there will be a downtime contingency. If the sampling programme has commenced, then the survey team will return to shore and assess the likely duration of the adverse weather conditions or equipment repair/replacement times. Alternative equipment/vessel suppliers will be identified in Darwin (in addition to the selected contractor) prior to works commencing, so that if possible, equipment/vessels can be replaced in the event of equipment/vessel issues.

### 5.9 Data management and reporting

Validation of analytical data will be undertaken as soon as results are received from the analytical laboratory. The relative standard deviation (RSD) will be determined for field triplicates and duplicates and the relative percentage difference (RPD) will be determined for laboratory duplicates. In accordance with the NAGD (Commonwealth of Australia 2009) laboratory duplicates that have a RPD of greater than  $\pm 35\%$  will be reanalysed, if possible, prior to the expiry of the analytical holding time. Likewise, field triplicates and duplicates that have an RSD of greater than  $\pm 50\%$  will be reanalysed. An interpretive quality control report will be provided by the analysing laboratory, highlighting any outliers to quality control procedures.

ProUCLT statistical software will be used to analyse the data. The reporting of the field and analytical data will comprise:

- documentation of all field procedures and data including core photographs and logs
- data validation
- comparison of the 95% Upper Confidence Limit (UCL) of contaminant concentrations in sediment in the dredge area with NAGD Screening Levels (as per Appendix A of the NAGD [Commonwealth of Australia 2009])
- if NAGD Screening Levels are exceeded, mean sediment contaminant concentrations will be compared with background concentrations.

### 5.10 Sampling and Analysis Plan Report

A SAP report will be submitted to DoE to comply with Condition 25 of the Commonwealth project approval (EPBC 2010/5304). The report will be used by the NTG as input into the Water Quality Management Plan (in accordance with the approval conditions detailed in Section 1.4).

The report will include a description of actual sampling locations and numbers, results including QA/QC assessment of both field and laboratory data, and an assessment of the results in accordance with the NAGD. The original laboratory certificates will also be included.

## Limitations

URS Australia Pty Ltd (URS) has prepared this report in accordance with the usual care and thoroughness of the consulting profession for the use of the NTG and only those third parties who have been authorised in writing by URS to rely on this Report.

It is based on generally accepted practices and standards at the time it was prepared. No other warranty, expressed or implied, is made as to the professional advice included in this Report.

It is prepared in accordance with the scope of work and for the purpose outlined in the proposal dated 1st July 2013.

Where this Report indicates that information has been provided to URS by third parties, URS has made no independent verification of this information except as expressly stated in the Report. URS assumes no liability for any inaccuracies in or omissions to that information.

This Report was prepared in November 2013, and is based on the conditions encountered and information reviewed at the time of preparation. URS disclaims responsibility for any changes that may have occurred after this time.

This Report should be read in full. No responsibility is accepted for use of any part of this report in any other context or for any other purpose or by third parties. This Report does not purport to give legal advice. Legal advice can only be given by qualified legal practitioners.

Except as required by law, no third party may use or rely on this Report unless otherwise agreed by URS in writing. Where such agreement is provided, URS will provide a letter of reliance to the agreed third party in the form required by URS.

To the extent permitted by law, URS expressly disclaims and excludes liability for any loss, damage, cost or expenses suffered by any third party relating to or resulting from the use of, or reliance on, any information contained in this Report. URS does not admit that any action, liability or claim may exist or be available to any third party.

Except as specifically stated in this section, URS does not authorise the use of this Report by any third party.

It is the responsibility of third parties to independently make inquiries or seek advice in relation to their particular requirements and proposed use of the site.

## **Appendix A Cross reference of Sampling and Analysis Plan to NAGD Appendix B**

NAGD Guidance	SAP Section
The objectives of the SAP, including data quality objectives.	1.5
A brief description of the dredging proposal, including the planned dredging area or areas, the dredging depths, the types of sediments involved and the final volume of material to be removed (in cubic metres) for sea disposal.	1.3
An evaluation of the history of the dredge area and its catchment, and available data on the sediments to be dredged.	2.1.2 2.2 3.1
A table showing the amounts to be dredged for each separate dredge area, as well as differentiating between clean, contaminated and potentially contaminated materials.	1.3
The <i>Contaminants List</i> , based on the history of the catchment and any previous sediment sampling.	3.2
Consideration of environmental factors potentially affecting contamination in the sediments (such as currents, bathymetry, grain-size) or which may limit or hinder the sampling program (for example depth, currents or waves, rocky bottom, weather, wildlife such as sharks, crocodiles or stingers, remoteness).	2.1.3 5.7
A rationale for the proposed sampling design, including maps showing the dredging area/s and the proposed sampling locations.	4
A contingency plan in case of adverse weather or critical failure of equipment.	5.8
The equipment (vessel, sampling, sub-sampling and testing gear, positioning equipment, sample containers, reports, charts and data forms) and personnel needed to implement the SAP, and a list of field measurements to be carried out.	5.2
A list of sample numbers, including field replicates and quality assurance samples, the approximate sampling locations and details of the position-fixing method, the proposed length of cores and depths of sub-samples from cores.	4 5.2 5.4
Step-by-step procedures for sampling and sub-sampling consistent with Appendix D of the Guidelines; the volume of sample required for analysis and the types and numbers of containers; procedures to ensure that samples are not contaminated from pollution sources on the survey boat.	5.1 5.2 5.3
Step-by-step procedures for sample handling, preservation, storage and QA/QC.	5.3
The laboratories to be used, a list of analyses required, the proposed analytical methods, the detection limits of the proposed methods, whether the methods will achieve the specified Practical Quantitation Limits (PQLs) in Table 1 <u>of the Guidelines</u> , laboratory replicates, certified reference materials, and QA/QC procedures.	5.3 5.5
Procedures for data management, data quality validation and any statistical routines proposed used.	5.9
